

Software Design and Development Coursework (Midterm)

Part 2: Unit testing activity

I will do unit testing in 3 parts:

1. **Trigonometric Functions**
2. **Exponential and Log functions**
3. **Other functions**

First, an assert function is setup to determine if the condition of each respective calculator function has been met, if it hasn't been met, an error message will be printed.

For each function, a test value is inputted to see if a correct math solution (given by me) is churned out by the function. If it matches, then the code is running smoothly or else a specific error message will be printed (i.e., log function error etc.)

All 3 sets of tests were run and the result was that all tests passed, as shown by the above message in the console.
